

Danger Level 1 - Low

Tendency: Constant avalanche danger →
on Tuesday 14 11 2023

Wind slab

1800m

Snowpack stability: **poor**

Frequency: **few**

Avalanche size: **small**

In the High, Western and Low Tatras at altitudes above 1800 m above sea level, there is still a **SMALL** avalanche danger, (1). Fresh snow has been blown by strong winds onto layers of older snow with which it is not sufficiently bound. The release of slab avalanches is possible especially under heavier loads on steep to very steep slopes. Spontaneous avalanches are not expected.

Snowpack

During the last snowfall, 10-20 cm fell on the mountains, which was blown by strong winds to the leeward slopes. The wind-drifted snow is deposited in the form of less stable snow slabs and pillows, with older snow not sufficiently bound. The height of wind_drifted snow reaches up to 50 cm.

Tendency

persistent condition
