

Danger Level 1 - Low

Tendency: Constant avalanche danger →
on Monday 03 02 2025

A predominantly favourable situation.

The snow cover is mostly packed and well consolidated. The avalanche situation is stable due to plus temperatures, rain and subsequent cooling. Avalanches can be released only sporadically, mainly on the northern slopes of the High and Western Tatras. Large additional loads are needed on steep and very steep slopes. In such a case a small avalanche or avalanche can be expected. The danger is rather due to the lack of snow, protruding rocks and rock thresholds.

Snowpack

Snow cover is below average for the time of year. Up to 1500m above sea level it is strongly local and oriented mainly to northern and shady places. The surface is mainly firn snow or crust. Due to rain and subsequent cooling, the surface is mostly hard, softening during the day on sunlit slopes. In the valleys beware of icy conditions.

Tendency

Stable.
