

Danger Level 2 - Moderate

Tendency: Constant avalanche danger →
on Tuesday 25 03 2025

Wet snow

Snowpack stability: **poor**

Frequency: **few**

Avalanche size: **medium**

Wind slab

Snowpack stability: **poor**

Frequency: **few**

Avalanche size: **medium**

Due to warming, the main avalanche problem is WET SNOW.

Moderate avalanche danger in the high altitudes of the High, Western and Low Tatras, 2nd degree. Small to medium-sized spontaneous avalanches from wet snow may occur on steep slopes during the day as the weather warms up. Hard snow slabs and pillows are present on north slopes, in couloirs, under saddles and rock faces, which may release an avalanche with a large additional load.

Snowpack

The snow cover is very heterogeneous due to variable precipitation, which is snow only at altitudes above 1800-2000 m above sea level. Below this line the snow is moist to wet, above it new snow is slightly increasing. Overall, however, only 5 to 10 cm. On the northern slopes at high altitudes (above 2000 m), snow slabs and pillows of varying hardness continue to occur. At altitudes up to 1500 m there is only patchy snow cover.

Danger Level 1 - Low

Tendency: Constant avalanche danger →
on Tuesday 25 03 2025

Wet snow

Snowpack stability: **poor**

Frequency: **few**

Avalanche size: **small**

There is only a small avalanche danger and only locally - on slopes with snow.

In Velká and Mala Fatra and in the eastern part of the Low Tatras there is only a SMALL avalanche danger, 1st degree. As a result of rain, the occurrence of wet snow avalanches on steep slopes is possible.

Snowpack

Most of the mountain ranges are already without snow cover. At altitudes up to 1400 m above sea level and on the southern slopes it is only discontinuous, at higher altitudes it is continuous, especially in gullies and cirques where it reaches a maximum of 50 cm. The snow is wet or damp throughout the day due to rain and warming temperatures.
